Appendix 3 – Binance UI 23

1. Executive Summary

This document contains needs analysis and usability test of **Binance** trading mobile application. This research was conducted to determine how effectively and efficiently users can perform five typical tasks: searching for an asset, performing a mock transaction, making a mock purchase, finding the bank transfer feature and working with the chatbot. Five participants were involved in the usability test, which resulted in 25 task observations.

The usability metrics that were used during the evaluation process included task completion, task completion time, errors, assistance needed, and satisfaction scores. All the participants were able to complete all five tasks, making the task completion score 100%. However, there was variance in the efficiency and user experience with different tasks. The sale simulation task took the longest time to complete on average with an average completion time of 72 seconds while the purchase simulation task had the most errors with 11 errors. The two transaction tasks were assisted by 60% of the participants.

In comparison, the chatbot took the least amount of time to complete an action, at an average of 10.4 seconds, did not need any participant help and gaining the highest satisfaction score of 4.6 out of 5. There were suggestions from participants that the complexity of the home page and purchase/sale transactions could pose problems.

Based on the results obtained, recommendations for simplifying the transactions workflow process, visual hierarchy of the home screen, as well as for increasing the discoverability of the chatbot are suggested. The recommendations are prioritized based on the usability data gathered from the study.

2. Introduction

2.1 Background

Functions like searching for financial assets, information view, transaction management, and support can be accessed through Binance. The reason being is that these applications have many different features and processes and therefore require clear navigation and interaction.

The ISO 9241-11:2018 presents the foundation of usability and defines usability within the context that the interactive system is used. The research hence focuses on three main aspects of usability; effectiveness, efficiency and satisfaction [1].

In the case of a trading program, task completion may not be enough to give a comprehensive insight on the usability of the program. The user might successfully accomplish the task despite getting lost along the way. This research takes into account the aspects of time, errors, help and satisfaction alongside task completion.

2.2 Purpose of the Study

Objectives of this research were to determine the users' needs and assess usability of a trading mobile application using usability testing techniques.

The objectives of the study included:

- Identification of users' previous experience and expectations while dealing with financial mobile applications.
- Assessment of users' performance in accomplishing common trading-app tasks.
- Evaluation of task completion rate, time, errors, help and satisfaction.
- Identification of specific usability issues from participants' comments and observations.
- Generation of useful recommendations based on the results.

The main research question was:

How effectively can users complete common tasks in a trading mobile application, and what usability issues affect their efficiency and satisfaction?

2.3 Scope and Limitations

The research examined five functions of Binance assets search, simulated buy, simulated sell, bank transfer, and chatbot communication. The research examined the usability of the user interface instead of evaluating the quality of the financial information, investment effectiveness, or financial decision making.

Purchasing and selling operations were considered to be usability test tasks without any actual transactions being made.

This research was conducted using only five people. This is a proper number for usability testing of a small qualitative nature as it is usually tested on about five users to find usability issues. Nevertheless, it is too few people to cover all traders app users [2].

Other shortcomings include the fact that the test subjects were not chosen as a statistically significant sample. Prior exposure to similar trading and banking applications could have an effect on the results. Furthermore, this experiment assessed one application and a set of tasks. Consequently, the results should be seen as an indicator of usability problems specific to the tested application.

3. Methodology

3.1 Research Design

Usability tests for user-centered usability were carried out through two stages; participant background survey, and task-based usability tests.

The survey was employed to understand how experienced the participants were with smartphone applications, trading applications, and the search for cryptocurrency and mobile banking. The usability test was done on how the participants were interacting with the interface selected.

Usability measures were of both qualitative and quantitative nature. Some of the quantitative measures included task completion, task time, errors, assistance and satisfaction. Some of the qualitative measures were gathered from the comments of the participants when undertaking the task.

These measures are similar to the usual measures of usability such as success rate, task time, errors and satisfaction [3].

3.2 Needs Analysis

The needs analysis was carried out to find out the user requirements in relation to the interaction with the Binance mobile app.

The participants were asked about:

- Experience in using smartphone apps.
- Confidence in using a new app.
- Past trading or investment apps usage.
- Past stock or cryptocurrency searches.
- Past mobile banking experience.
- Financial asset search experience.
- Digital buying and selling experience.

According to the questionnaire findings, all the five participants had experience using trading/investment apps and mobile banking applications. However, four out of the five participants had previously searched for stocks/cryptocurrencies using an app on their phone.

However, they were not as familiar with particular financial functionalities. This was helpful in gaining insights into some of the challenges experienced while buying and selling.

3.3 Data Collection

Five participants were used in the usability test. All participants performed the same five tasks in order to compare their results.

In each task, the following data was collected:

- Status of completion.
- Time taken for completion (in seconds).
- Number of errors.
- Need for assistance.
- Ease of use on a scale of 1 to 5.
- Comments from participants.

The satisfaction scale was:

Score	**Meaning**
1	Very Difficult
2	Difficult
3	Neutral
4	Easy
5	Very Easy

Participants' comments were also noted since, at times, quantitative data might not provide a reason for why the participant had problems.

3.4 Participant Recruitment and Screening

Participants first answered a questionnaire for background before executing the usability tests. Participants' background was established by verifying their familiarity with the smartphone app, trading app, and mobile banking.

The study employed participants labeled as P1-P5 instead of using their names in the result section. This aided in keeping an easy distinction between participants' identity and their usability test result.

3.5 Usability Testing Tasks

Every participant was subjected to the following five tasks:

Task 1 - Search

The participant was required to search for a particular cryptocurrency using the search feature within the application.

Task 2 – Simulated Buy

The participant was asked to find the buy feature within the application and go through the entire process until the confirmation step without making any real purchase.

Task 3 – Simulated Sell

The participant was asked to find the sell feature within the application and go through the entire process until the confirmation step without making any real sale.

Task 4 – Bank Transfer

The participant was asked to find the bank transfer feature within the application and find the necessary information needed. No real bank transfer was made.

Task 5 – Chatbot

The participant was asked to find the chatbot feature within the application and make use of the feature to answer a simple support question.

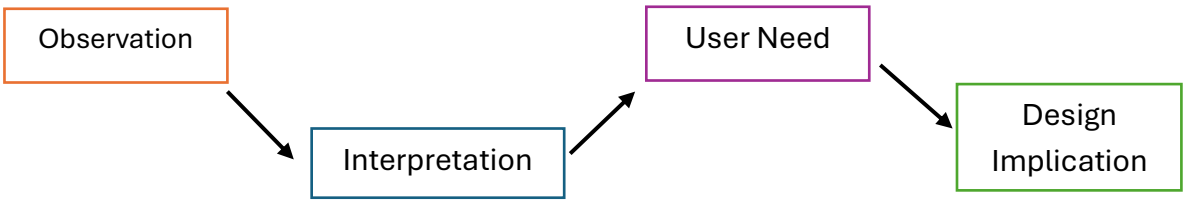

The above-mentioned task sequence was followed by all participants to ensure consistency.

3.6 Data Analysis

The collected data were analyzed with descriptive statistics. Percentage of task completion was used to analyze effectiveness. Average time for completing tasks and errors committed were used to analyze efficiency. Requirements for assistance and satisfaction were used to find out the areas where participants had problems.

Participant feedback was analyzed along with the quantitative data. It helped to link usability issues to concrete evidence rather than simply use quantitative data.

The analysis followed the general structure:

This method assisted in differentiating what the users were doing from the understanding of why the usability problem might have happened.

4. Findings

4.1 User Needs and Expectations

The findings from the questionnaires indicated that all five of the participants had prior exposure to trading or investment apps and mobile banking apps. Four of the participants (80%) had prior exposure to searching for stocks or cryptocurrencies through mobile apps.

Three of the participants (60%) frequently used smartphone apps, and three of the participants (60%) felt confident when trying out new mobile apps.

However, respondents claimed that they were less familiar with particular operations, like searching for cryptocurrencies and making transactions online. Thus, it can be assumed that even if users have experience of using mobile applications in general, they need clear instructions for performing financial operations.

It follows from the results that users require:

- Clear navigation
- Legible labels for financial functions.
- Simple transaction process.
- Confirmation of each step.
- Discoverability of additional functions.
- Not overwhelming interface.

4.2 Usability Findings

The overall results are presented below.

Task	Completion	Average Time	Errors	Assistance	Satisfaction
Search	100%	12.4 sec	4	20%	4.2/5
Simulated purchase	100%	69.4 sec	11	60%	3.0/5
Simulated sale	100%	72.0 sec	8	60%	3.0/5

Bank transfer	100%	45.4 sec	4	20%	3.8/5
Chatbot	100%	10.4 sec	2	0%	4.6/5

However, all 25 attempts to perform the tasks were completed. Nonetheless, the results reveal that the completion rate alone is not the whole story of usability.

Tasks involving purchase and selling took considerably more time and help than the search and chatbot tasks.

4.3 Task Completion

Completion of all five tasks was 100%. This means that all users have been able to complete the assigned tasks.

This is a strong indicator of effectiveness in terms of task completion in the current conditions. Nonetheless, one cannot say that all the tasks were equally usable, as the purchase task had 11 mistakes and needed help from 60% of the participants although its completion was 100%.

This proves that task completion needs to be assessed alongside other factors related to usability.

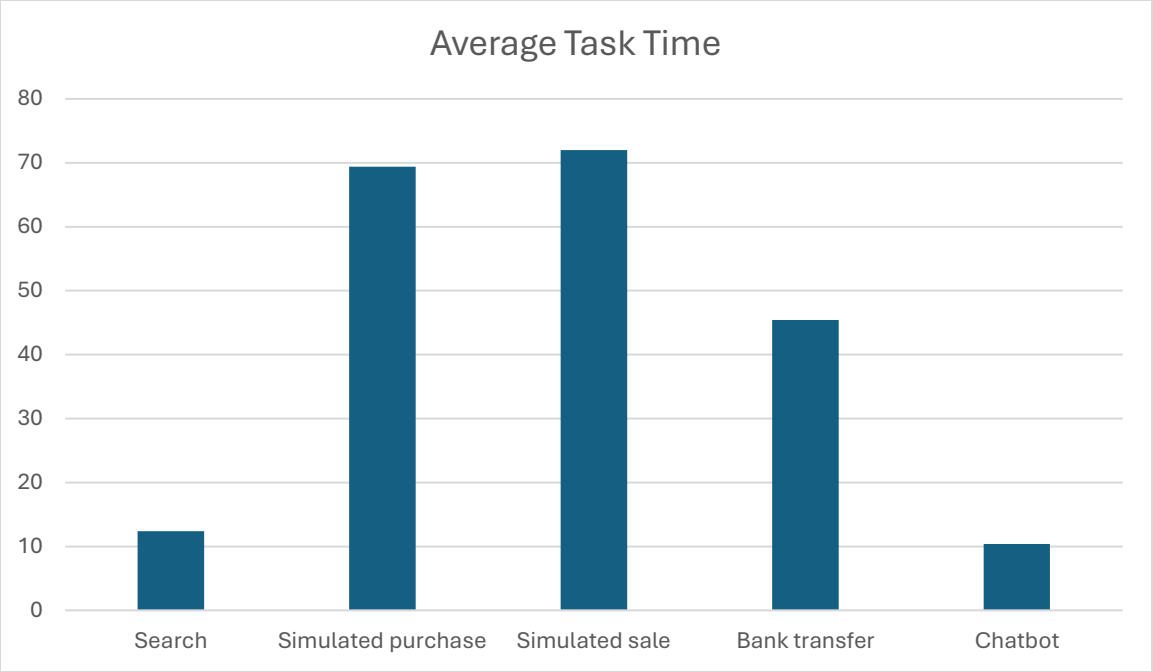

4.4 Task Time

The average duration of the tasks varied significantly for the five different tasks.

The chatbot took the shortest time to be accomplished, averaging 10.4 seconds, and was followed by the search task, which averaged 12.4 seconds. The bank transfer took an average of 45.4 seconds.

The purchase task averaged 69.4 seconds, while the sale task took the longest time, averaging 72 seconds.

The time taken to complete the purchase and sales tasks longer is an indication that these tasks required more interaction from the participants.

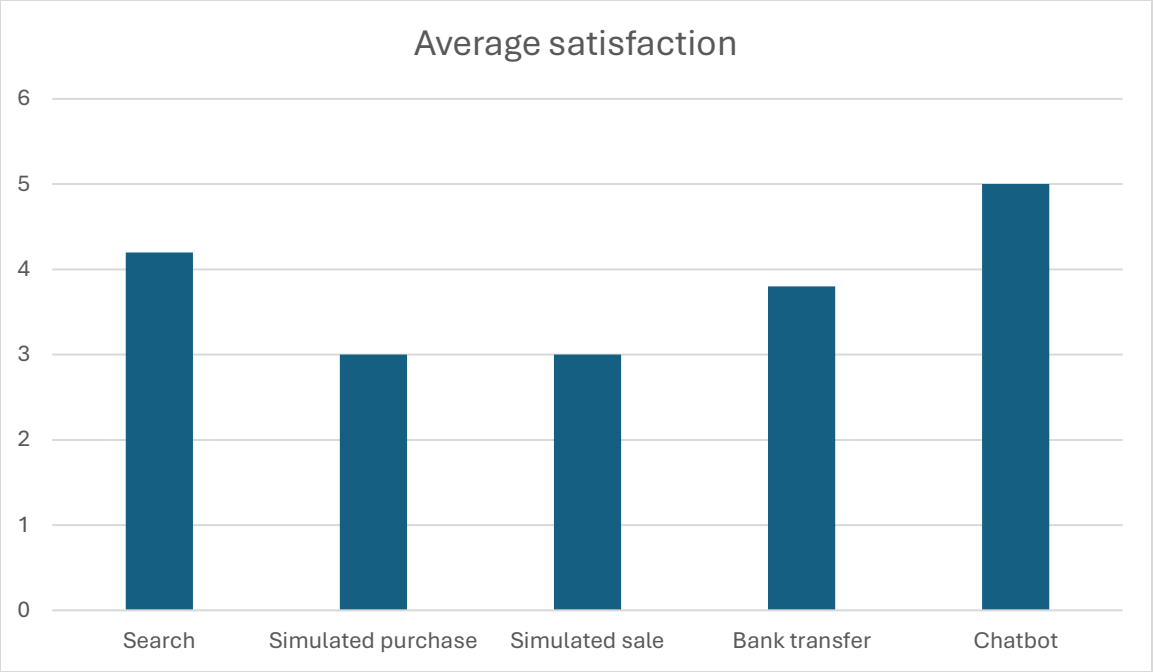

4.5 User Satisfaction

Satisfaction was also significantly different across the tasks.

The chatbot received the highest rating of 4.6 out of 5, search got 4.2/5, bank transfer was rated 3.8/5, whereas purchase and sale were rated 3.0/5 each.

The low satisfaction ratings for purchase and sale can be explained by the higher number of errors and need for assistance for completing those tasks.

However, it must be stressed that the satisfaction score cannot be regarded as an objective measure. Satisfaction is highly subjective, and it makes sense only in conjunction with other measures such as performance.

4.6 Perceived Ease of Use

Participant comments provided additional evidence about perceived ease of use.

For the purchase task, participants commented:

- “Where do I start?”
- “This might be a long process.”
- “It is bit different than other apps.”
- “Seems like too many steps.”
- “This is hard.”

For the sale task, participants commented:

- “How do I sell?”
- “Bit confusing.”
- “UI is bit complicated.”
- “Too many steps.”
- “I don't think I can complete this.”

From these statements, it is clear that there were challenges faced by the participants in the comprehension of the transaction process.

In relation to the search feature, it appeared to be more straightforward than the transaction process. From one participant’s point of view, he termed it “Simple”. But, P4 and P5 talked about

the complexity of information available in the homepage. According to P5, he found the homepage complex since there was so much to look at.

For the chatbot, it appears that there were no challenges as they referred to it as “Easy” and “Simple.” From the feedback provided by some participants, they found it hard to identify the chatbot at first.

4.7 Overall Analysis

The central result from this research is that task completion is consistently effective while efficiency and satisfaction have highly varied results.

Purchase and sales processes were the processes with the most problems in terms of usability. The highest average task duration, necessity for assistance and lowest satisfaction scores were registered by these processes. Purchase process also resulted in the highest number of errors.

Qualitative data is also consistent with quantitative results as participants noted confusion, slowness and complexity of transactions.

5. Recommendations

5.1 Recommendation 1 - Simplify the Purchase Workflow

Purchase process can be made simpler by removing all unnecessary steps and identifying the next step that needs to be taken.

Justification for this recommendation is based on the fact that the average time of completion of purchase task is 69.4 seconds, number of errors is 11, 60% assistance requirement and 3.0/5 satisfaction score. Statements like “Where do I start?” and “Too many steps” made by participants reinforce this recommendation.

It will make the steps easy to follow and minimize the mental effort needed for process completion.

Priority: High

5.2 Recommendation 2 - Improve the Sale Workflow

The sales flow must be redesigned to ensure that it is easier to understand and navigate.

The sales activity took the longest time for completion with an average time of 72 seconds and had eight mistakes and 60% of participants requiring assistance. Participants also found the user interface confusing and complicated.

Thus, the sales process needs to have a definite starting point and predictable action sequence.

Priority: High

5.3 Recommendation 3 - Improve Home-Screen Information Hierarchy

The home screen should be assessed to minimize unnecessary visual complexity.

As mentioned by P4, the home screen “was a bit too much”, and according to P5, “it is very complicated” and “has too many things to look at.”

Commonly used features need to be made more visually prominent, while the rest can be moved somewhere else.

Priority: Medium

5.4 Accessibility Improvements

The issue of accessibility must also be analyzed in relation to the usability findings. In this regard, WCAG 2.2 offers accessibility recommendations on topics such as text appearance, contrast, labels and interactions [4].

The suggestions that can be made for the interface in question are as follows:

- Employing legible text.
- Providing appropriate contrast between text and background.
- Using informative labels instead of icon-only solutions.
- Making buttons and interactive elements distinguishable.
- Providing informative error messages.
- Not presenting excessive information at once.
- Keeping navigation consistent across screens.
- Ensuring the proper understanding of functions when text enlargement is used.

These measures will be especially beneficial for those users who feel less comfortable with financial applications.

5.5 Prioritisation

Prioritization of the recommendations was done based on the evidence found during the usability tests.

- **High priority**

  Purchase workflow and sale workflow

  This task scored highest in both completion time and the presence of errors, assistance and low satisfaction.

- **Medium priority**

  Organization of home screen and discoverability of chatbot

  While these problems were raised during the test, they did not prevent the task from being completed.

This prioritization should be considered as a decision made for design planning, based on the evidence from the study conducted in this particular case.

6. AI-Assisted Critique Evidence

Stage	Prompt	AI Response Summary	Accepted	Modified	Rejected	Reason
Initial	What are the limitations of using only five participants in a usability study?	Five participants can be appropriate for an early exploratory usability test, particularly for identifying obvious usability issues, but the results should be treated as preliminary rather than representative of the entire target population.	Yes	No	No	It was helpful when deciding appropriate amount of participants.
Refinement 1	How can task completion, task time, errors and satisfaction be used to evaluate usability?	If most users complete a task successfully, take little time, make few errors, and report high satisfaction, the system is likely to have good usability.	Yes	No	No	It was helpful when deciding the success rate.
Refinement 2	How can qualitative participant comments be analysed alongside quantitative usability data?	Quantitative data tells you "what happened," while qualitative comments help explain "why it happened." Combining both provides a more complete evaluation of usability.	Yes	No	No	It was helpful to get some insight apart from the numerical values.

What are the limitations of using only five participants in a usability study?

Using only **five participants** in a usability study can provide useful early insights, but it has several limitations:

1. **Limited generalisability** – Five participants may not represent the wider target user population, so the findings cannot confidently be applied to everyone.
2. **Small sample diversity** – Important differences in age, experience, technical ability, or user needs may not be captured.
3. **Risk of missing usability problems** – Some problems may only appear with particular types of users. With five participants, less common issues can easily be overlooked.
4. **Limited statistical analysis** – A sample of five is generally too small for reliable statistical conclusions or meaningful comparisons between groups.
5. **Participant bias** – The characteristics or behaviour of a small number of participants can have a large influence on the overall findings.
6. **Difficulty identifying patterns** – Researchers may observe recurring issues, but it is harder to determine whether those patterns are genuinely representative of the broader population.
7. **Reduced reliability for subgroup comparisons** – If the study needs to compare groups, such as younger versus older users or experienced versus inexperienced users, five participants may be insufficient.

In summary: Five participants can be appropriate for an **early exploratory usability test**, particularly for identifying obvious usability issues, but the results should be treated as **preliminary rather than representative of the entire target population**.

How can task completion, task time, errors and satisfaction be used to evaluate usability?

These four measures evaluate usability from different perspectives:

Measure	What it evaluates	Example
Task completion	Whether users can successfully complete a task	4 out of 5 users successfully book a ticket
Task time	How efficiently users can complete the task	Users take an average of 2 minutes to book a ticket
Errors	How often users make mistakes or encounter problems	Users enter the wrong information twice
Satisfaction	How users feel about the experience	Users rate the system 4/5 for ease of use

Together, they show:

- **Effectiveness:** Task completion shows whether users can achieve their goals.
- **Efficiency:** Task time shows how quickly and easily they can do so.
- **Error rate:** Shows whether the interface causes confusion or mistakes.
- **User satisfaction:** Shows whether users find the experience comfortable, easy, and acceptable.

For example, if **most users complete a task successfully, take little time, make few errors, and report high satisfaction**, the system is likely to have good usability.

How can qualitative participant comments be analysed alongside quantitative usability data?

Qualitative participant comments can be analysed alongside quantitative usability data by **combining numerical results with explanations of why users experienced those results**.

For example:

Quantitative data	Qualitative comment	Interpretation
Task completion: 80%	"I wasn't sure which button to select."	The interface may have unclear navigation.
Average task time: 3 minutes	"I had to search around to find this option."	The layout may be reducing efficiency.
Errors: 4 per participant	"The instructions were confusing."	Poor instructions may be contributing to errors.
Satisfaction: 3/5	"It works, but it doesn't feel easy to use."	The system is functional but could provide a better user experience.

A simple analysis process

1. **Analyse quantitative data** – Calculate task completion rates, average task times, error rates, and satisfaction scores.
2. **Identify problem areas** – Look for tasks with low completion, long completion times, frequent errors, or low satisfaction.
3. **Review participant comments** – Group comments into common themes such as *navigation, confusing labels, layout, instructions,* or *feedback.*
4. **Connect the two types of evidence** – Use partic[illegible]t comments to explain the numerical findings.
5. **Look for consistency or differences** – For example, high satisfaction scores combined with long task

Appendix 1 – Screening Questionnaire

Participant Screening and Background Questionnaire

5 Responses 01:16 Average time to complete Closed Status

1. How often do you use smartphone applications?

Rarely	0
Occasionally	1
Frequently	3
Several times a day	1

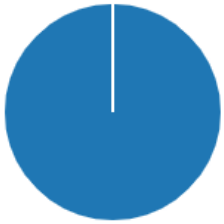

2. How confident are you when using a new mobile application for the first time?

1 – Not confident	0
2 – Slightly confident	1
3 – Moderately confident	1
4 – Confident	3
5 – Very confident	0

3. Have you previously used a trading or investment mobile application?

Yes	5
No	0

4. If yes, how frequently have you used a trading or investment application?

Rarely	3
Occasionally	2
Frequently	0
Very frequently	0
Not applicable	0

5. Have you previously searched for information about stocks or cryptocurrencies using a mobile application?

Yes	4
No	1

6. Have you previously used a mobile banking application to manage your finances or make a bank transfer?

Yes	5
No	0

7. How familiar are you with searching for financial assets such as stocks or cryptocurrencies in a mobile application?

1 – Not familiar	1
2 – Slightly familiar	2
3 – Moderately familiar	2
4 – Familiar	0
5 – Very familiar	0

8. How familiar are you with buying or selling financial assets through a digital platform?

1 – Not familiar	1
2 – Slightly familiar	1
3 – Moderately familiar	3
4 – Familiar	0
5 – Very familiar	0

9. Do you regularly use a smartphone?

Yes	5
No	0

10. Are you comfortable completing simple tasks on a mobile application while being observed for a usability study?

Yes	5
No	0
